Harvard Department of Physics

(Dated: May 14, 2015)

We present a formal derivation of the confinement induced resonance for particles in a lower dimension. The generic  $T$ -matrix method is used to calculate the  $S$ -wave collisional property between two ultra-cold atoms. We show the breakdown of a naive approach to describe such low dimensional system near a Feshbach resonance and perform a real three dimensional calculation to include additional effect from the confinement. The normalization of the high energy states in such cases are done by comparing to the result in free space.

## 1. INTRODUCTION

In the field of ultra-cold atoms and molecules, the collisional properties between the particles play an important role for cooling into quantum degeneracy. The tunability of the scattering length using Feshbach resonance opens the door for engineering the interaction and using it as a source of correlation and entanglement in a many-body system.

## 2. FESHBACH RESONANCE

Feshbach resonance is a way to tune the interaction between two atoms. It appears as a divergence in the scattering length when the energy of a molecular bound state matches or is closed to the energy of the free atom state. The relative energy between the molecular and atomic is usually tuned using the magnetic field and the difference in Zeeman effect between the two states although optical dressing has also been used on excited metastable state.

In this section, we will describe a formal way to calculate the properties of  $S$ -wave scattering at low temperature. We will then apply this framework to a simplified model of Feshbach resonance consists of a open channel for the free atomic state and a closed channel for the molecular bound state.

### 2.1. Wave function of a scattering process

In a scattering problem, the wave function can be broken into the incident wave  $\Psi_i$  and the scattered wave  $\Psi_s$  where the incident wave is usually a plain wave

$$\Psi_i = e^{i\vec{k}\cdot\vec{r}}$$

and the scattered wave can be expressed as a spherical wave centered around the scattering core ( $\vec{r}=0$ )

$$\Psi_s = \frac{f(\theta)}{r} e^{ik'r}$$

For all the discussion in this paper, we are taking the limit of low temperature (i.e. low kinetic energy) in which case the scattering is limited to  $S$ -wave (angular momentum  $L^2 = 0$ ). We also assume that the interaction is short range so that the behavior is regular for long wavelength and we can take the limit of  $k \rightarrow 0$ . In such a limit, the total wave function can be written as

$$\begin{aligned}\Psi(\vec{r}) &= \Psi_i(\vec{r}) + \Psi_s(\vec{r}) \\ &\approx e^{i\vec{k}_0\cdot\vec{r}} - \frac{a}{r}\end{aligned}$$

where  $a$ , which describe the fraction being scattered, is defined as the scattering length. In order to solve this problem, it is convenient to express the Schrödinger equation in the momentum space

$$\frac{k^2 - k'^2}{m} \Psi_s(\vec{k}') = U(\vec{k}', \vec{k}) + \int \frac{d^3 k''}{(2\pi)^3} U(\vec{k}', \vec{k}'') \Psi_s(\vec{k}'')$$

where  $U(\vec{k}', \vec{k})$  is the Fourier transform of the interaction

$$U(\vec{k}', \vec{k}) = \int d^3 \vec{r} \int d^3 \vec{r}' U(\vec{r}' - \vec{r}) e^{i\vec{k}'\cdot\vec{r}'} e^{-i\vec{k}\cdot\vec{r}}$$

and we have used the fact that the interaction is short range and the energy of the state is determined by the long distance behavior of the incident state  $E_k = k^2/2m$ .

### 2.2. $T$ -Matrix

The  $T$ -matrix is defined as a map from the initial state of the scattering (which is a  $\delta$  function in  $k$  space in our case) to the final state. It is defined as

$$T(\vec{k}', \vec{k}) = U(\vec{k}', \vec{k}) + m \int \frac{d^3 k''}{(2\pi)^3} \frac{U(\vec{k}', \vec{k}'')}{k^2 - k''^2 + i0} T(\vec{k}'', \vec{k})$$

where the  $+i0$  denotes a infinitesimal quantity to ensure that we have outgoing waves. Note the similarity with

---

\*Electronic address: [yuyichao@mit.edu](mailto:yuyichao@mit.edu); URL: <http://yyc-arch.org/>

the equation satisfied by the scattered wavefunction. Using the  $T$ -matrix, we can express the scattered wavefunction as

$$\Psi_s(\vec{k}') = \frac{m}{k^2 - k'^2 + i0} T(\vec{k}', \vec{k})$$

And we can also define the scattering amplitude as

$$f(\vec{k}', \vec{k}) = -\frac{m}{4\pi} T(\vec{k}', \vec{k})$$

For the problem we are considering, we will take the limit of  $k, k' \rightarrow 0$ , therefore

$$\Psi_s(\vec{k}') = \frac{m}{k^2 - k'^2 + i0} T(0, 0)$$

In real space

$$\begin{aligned} \Psi_s(\vec{r}) &= \int \frac{d^3k'}{(2\pi)^3} \frac{m e^{i\vec{k}' \cdot \vec{r}}}{k^2 - k'^2 + i0} T(0, 0) \\ &= -\frac{m e^{ikr}}{4\pi r} T(0, 0) \end{aligned}$$

and by comparing to the form of  $\Psi_s$  at low temperature we have  $f(k \rightarrow 0) = -a$

### 2.3. Effective interaction

Although the interaction potential between two atoms can be very strong and hard to calculate, they are usually very short range and their precise behavior can only affect the states with a large  $k$ . Therefore, for the purpose of low energy collision in which both the initial and final state has a small  $k$ , it is useful to introduce a simple effective potential that can be used to describe these low energy process below a cut-off energy  $\varepsilon_c$ . Let the corresponding cut-off in wave vector and length be  $k_c^2/m = \varepsilon_c$  and  $R_c = k_c^{-1}$ , we can write a effective potential  $\tilde{U}(\vec{k}', \vec{k})$

$$\tilde{U}(\vec{k}', \vec{k}) = U(\vec{k}', \vec{k}) + m \int_{k_c} \frac{d^3k''}{(2\pi)^3} \frac{U(\vec{k}', \vec{k}'')}{k^2 - k''^2 + i0} \tilde{U}(\vec{k}'', \vec{k})$$

And express the scattering process using this potential and only low energy states as

$$T(\vec{k}', \vec{k}) = \tilde{U}(\vec{k}', \vec{k}) + m \int_{k_c} \frac{d^3k'}{(2\pi)^3} \frac{\tilde{U}(\vec{k}', \vec{k}')}{k^2 - k'^2 + i0} T(\vec{k}', \vec{k})$$

The effective potential can now be any short range function that gives the correct scattering amplitude. As the simplest potential, the one that is usually taken is a  $\delta$  function

$$U(\vec{r}) = U_0 \delta^3(\vec{r})$$

Using which we can write the equation for the scattering amplitude

$$\begin{aligned} f(\vec{k}', \vec{k}) &= -\frac{mU(\vec{k}' - \vec{k})}{4\pi} \\ &+ m \int_{k_c} \frac{d^3k''}{(2\pi)^3} \frac{U(\vec{k}' - \vec{k}'')}{k^2 - k''^2 + i0} f(\vec{k}'', \vec{k}) \end{aligned}$$

Since the major contribution of the integral comes from when  $|k| = |k''|$ , we can replace  $f(\vec{k}'', \vec{k})$  by  $f(k)$  therefore

$$\begin{aligned} \frac{1}{f(k)} &= -\frac{4\pi}{mU_0} + 4\pi \int_{k_c} \frac{d^3k''}{(2\pi)^3} \frac{1}{k^2 - k''^2 + i0} \\ &= -\frac{4\pi}{mU_0} + \frac{2}{\pi} \left( -k_c - \frac{k}{2} \ln \left( -\frac{k_c - k - i0}{k_c + k + i0} \right) \right) \\ &\approx -\frac{4\pi}{mU_0} + \frac{2}{\pi} \left( -k_c - \frac{i\pi k}{2} + \frac{k^2}{k_c} \right) \end{aligned}$$

therefore

$$a = \frac{\pi}{2} \frac{mU_0}{mU_0 k_c + 2\pi^2}$$

Note that non of the cut-off  $k_c$  or the effective potential  $U_0$  is physical but the scattering length  $a$  is. Any physical process calculated with the effective model should only depend on physical quantities and  $k_c$  and  $U_0$  should drop out.

### 2.4. Multichannel scattering and Feshbach resonance

$$\hat{H}_0 |\vec{k}\rangle =$$
